1 Normal Model, Mixture of Normal Model with Semi-Conjugate Prior

Exercise: The data `rainfall.dat` consist of daily records, from the beginning of 1948 to the end of 1983, of precipitation (rain or snow in units of 1 inch, and records of zero 100 precipitation are excluded) at Snoqualmie Falls, Washington. Analyze the data using the following two models.

- a) Assume the daily precipitation y_1, \dots, y_n are independent normally distributed, $y_1, \dots, y_n | \mu, \sigma^2 \sim \mathcal{N}(\mu, \sigma^2)$ where both μ and σ^2 are unknown. Let $\mu \sim \mathcal{N}(\mu_0, \tau_0^2)$ independently of $\sigma^2 \sim \text{Inv} - \chi^2(\nu_0, \sigma_0^2)$
 - Implement (code!) a Gibbs sampler that simulates from the joint posterior $p(\mu, \sigma^2 | y_1, \dots, y_n)$. The full conditional posteriors are given on the slides from Lecture 7.
 - Analyze the daily precipitation using your Gibbs sampler in (a)-i. Evaluate the convergence of the Gibbs sampler by suitable graphical methods, for example by plotting the trajectories of the sampled Markov chains.
- b) Let us now instead assume that the daily precipitation y_1, \dots, y_n follow an iid two-component **mixture of normals** model:

$$p(y_i | \mu, \sigma^2, \pi) = \pi \mathcal{N}(y_i | \mu_1, \sigma_1^2) + (1 - \pi) \mathcal{N}(y_i | \mu_2, \sigma_2^2)$$

where

$$\mu = (\mu_1, \mu_2) \text{ and } \sigma^2 = (\sigma_1^2, \sigma_2^2)$$

Use the Gibbs sampling data augmentation algorithm in `NormalMixtureGibbs.R` (available under Lecture 7 on the course page) to analyze the daily precipitation data. Set the prior hyperparameters suitably. Evaluate the convergence of the sampler.

- c) Plot the following densities in one figure:

- A histogram or kernel density estimate of the data.
- Normal density $\mathcal{N}(\mu, \sigma^2)$ in (a)
- Mixture of normals density $p(y_i|\mu, \sigma^2, \pi)$ in (b)

Use the posterior mean value for all the parameters.

1.1 Normal Model

1.1.1 Gibbs Sampler Implementation

First we load the data and set the parameters for our prior.

```
#####
# Exercise 1.a i)
#####

rainfall_data = read.table("data/rainfall.dat", header=FALSE)

# Prior Parameters (slides page 15)
# These are basically random, guessed or from the data
# mu
mu_0 = 0
tau_sq_0 = 1

# sigma_sq
nu_0 = 1
sigma_sq_0 = 1 # sigma is 1/nu_0
```

This is a custom function to sample from the inverse chi squared distribution.

```
crinvchisq = function(n, df, s_sq) {
  samples = rchisq(n, df)
  # These are draws from the inverse chi squared
  sigma_sq = (df - 1) * s_sq / samples
  return(sigma_sq)
}
```

This is the Gibbs Sampler, which takes the number of draws, a default σ (as both σ and μ depend on each other we need to start somewhere) and some more parameters to calculate the posterior parameters.

```
gibbs_sample = function(nDraws, data, default_sigma, tau_sq_0, mu_0, nu_0, sigma_sq_0) {

  # Posterior Parameters (Taken from lecture 2 slide 4)
  n = length(data)
  mu_n = mean(data) + mu_0
  nu_n = nu_0 + n
  default_sigma_sq = default_sigma^2

  # To store all iterative results
  values_df = data.frame(matrix(NA, nrow = nDraws, ncol = 2))

  # To save current iterative results
  values = list(mu = NaN, sigma_sq = default_sigma_sq)

  # As mu depends on sigma and sigma depends on mu, we need one initial value to start.
  # In this implementation the default value to start with is sigma_sq.
```

```

for (i in 1:nDraws) {
  tau_sq_n = 1 / ((n/values$sigma) + (1/tau_sq_0))
  values$mu = rnorm(1, mu_n, sqrt(tau_sq_n))
  values$sigma_sq = crinvchisq(1, nu_n, (nu_0*sigma_sq_0 + sum((data - values$mu)^2))/(n + nu_0))
  values_df[i,] = values
}

colnames(values_df) = c("mu", "sigma_sq")
return(values_df)
}

```

Now we call our Gibbs Sampler and print the draws.

```

res = gibbs_sample(nDraws = 100,
  data = rainfall_data$V1,
  default_sigma = 40,
  tau_sq_0 = tau_sq_0,
  mu_0 = mu_0,
  nu_0 = nu_0,
  sigma_sq_0 = sigma_sq_0)

kable(head(res))

```

	mu	sigma_sq
	31.99015	1532.776
	31.94522	1532.958
	31.85069	1560.033
	31.76912	1547.209
	32.66617	1554.557
	32.30512	1554.941

1.1.2 Analysing the Precipitation

This is the traceplot for μ including the trailing mean. We can see that the mean converges.

The same for σ^2 .

1.2 Mixture Normal Model

```

Helper functions

This is the traceplot for μ .

This is the traceplot for σ .

Parameters of the Prior: Without looking at the data we have no clear idea of the priors should look like. We can assume that probably the mean is greater than 0, but about the variance or α we do not really have an idea. That's why we leave the parameters as they are. The default implementation actually takes the variance of the data for the prior, where we think that's not 100 percent appropriate but it depends on the problems one tackles in the real world of course. In addition it shouldn't matter that much because after the burn-in period the prior shouldn't matter any more to discover the posterior density function.

Convergence: As we can see from the different trace plots the parameters actually converge the same as in the previous exercise. More iterations will make the result more accurate but we set it to a low amount of iterations to have a better zoom on the start of the process to observe the burn-in period.

1.3 Graphical Comparison

The following plot shows the densities of the data and the two models.

2 Metropolis Random Walk for Poisson Regression

Exercise: Consider the following Poisson regression model

$$y_i | \beta \sim \text{Poisson} [\exp(x_i^T \beta)], i = 1, \dots, n$$

where y_i is the count for the i th observation in the sample and x_i is the p -dimensional vector with covariate observations for the i th observation. Use the data set `eBayNumberOfBidderData.dat`. This dataset contains observations from 1000 eBay auctions of coins. The response variable is `nBids` and records the number of bids in each auction. The remaining variables are features/covariates (\mathbf{x}):

- **Const** (for the intercept)
- **PowerSeller** (is the seller selling large volumes on eBay?)
- **VerifyID** (is the seller verified by eBay?)
- **Sealed** (was the coin sold sealed in never opened envelope?)
- **MinBlem** (did the coin have a minor defect?)
- **MajBlem** (a major defect?)
- **LargNeg** (did the seller get a lot of negative feedback from customers?)
- **LogBook** (logarithm of the coins book value according to expert sellers. Standardized)
- **MinBidShare** (a variable that measures ratio of the minimum selling price (starting price) to the book value. Standardized).

- a) Obtain the maximum likelihood estimator of β in the Poisson regression model for the eBay data [Hint: `glm.R`, don't forget that `glm()` adds its own intercept so don't input the covariate `Const`]. Which covariates are significant?

- b) Let's now do a Bayesian analysis of the Poisson regression. Let the prior be $\beta \sim \mathcal{N}[\mathbf{0}, 100 \cdot (X^T X)^{-1}]$ where \mathbf{X} is the $n \times p$ covariate matrix. This is a commonly used prior which is called Zellner's g-prior. Assume first that the posterior density is approximately multivariate normal:

$$\beta|y \sim \mathcal{N}[\tilde{\beta}, J_y^{-1}(\tilde{\beta})],$$

where $\tilde{\beta}$ is the posterior mode and $J_y(\tilde{\beta})$ is the negative Hessian at the posterior mode. $\tilde{\beta}$ and $J_y(\tilde{\beta})$ can be obtained by numerical optimization (`optim.R`) exactly like you already did for the logistic regression in Lab 2 (but with the log posterior function replaced by the corresponding one for the Poisson model, which you have to code up.).

- c) Now, let's simulate from the actual posterior of β using the Metropolis algorithm and compare with the approximate results in b). Program a general function that uses the Metropolis algorithm to generate random draws from an arbitrary posterior density. In order to show that it is a general function for any model, I will denote the vector of model parameters by θ . Let the proposal density be the multivariate normal density mentioned in Lecture 8 (random walk Metropolis):

$$\theta_p|\theta^{(i-1)} \sim \mathcal{N}(\theta^{(i-1)}, c \cdot \Sigma),$$

where $\Sigma = J_y^{-1}(\tilde{\beta})$ obtained in b). The value c is a tuning parameter and should be an input to your Metropolis function. The user of your Metropolis function should be able to supply her own posterior density function, not necessarily for the Poisson regression, and still be able to use your Metropolis function. This is not so straightforward, unless you have come across *function objects* in R and the triple dot (`...`) wildcard argument. I have posted a note ([HowToCodeRWM.pdf](#)) on the course web page that describes how to do this in R.

Now, use your new Metropolis function to sample from the posterior of β in the Poisson regression for the eBay dataset. Assess MCMC convergence by graphical methods.

2.1 Maximum Likelihood Estimator

2.2 Bayesian Analysis of the Poisson Regression

2.3 Simulate from the Actual Posterior Using the Metropolis Algorithm
